

Abstract of the Disclosure:

In the prior art, broadband terminals are supplied to the Internet via an associated router. Incorporated between the router and the Internet are selection servers for selecting
5 services (Service Selection) which are used to handle the entire traffic for the Internet. A problem with this is that the selection server is configured in the communication path to the Internet, which means that the dynamics of access are reduced. The invention provides a remedy for this by arranging the selection server parallel to the router, which removes it from the path between the router and the Internet.
